Operating System Labs

Yuanbin Wu CS@ECNU

Operating System Labs

- Project 3
 - Due: 5 Dec.
- New course page!
 - https://github.com/ecnu-oslab/ecnuoslab-up/blob/main/21-Fall/index.md
 - https://hub.fastgit.org/ecnu-oslab/ecnuoslab-up/blob/main/21-Fall/index.md

Operating System Labs

- Overview of concurrency
 - Thread
 - Two scenarios of concurrency control
 - Locks
 - Condition Variables
- Project 3 parta

Process and Thread

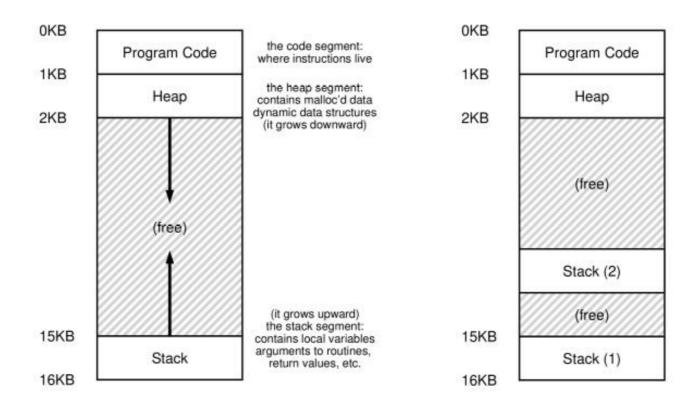

- In Linux, threads are processes with shared address space
 - clone() system call with CLONE_THREAD
- Program Counter (PC)
 - Process: one PC
 - Threads: multiple PCs
- Context switch
 - Process: PCB
 - Thread: TCBs in PCB

Process and Thread

Stack

Process: one stack

Thread: multiple stacks (thread local storage)

Process and Thread

- Why threads
 - Accelerate performance
 - Multiple processors, multi-core
 - Light Weight
 - Faster creating and managing than processes
 - Efficient communication
 - Shared address space

Example 1: multithread

```
#include <stdio.h>
#include <assert.h>
#include <pthread.h>
void *mythread(void *arg) {
  printf("%s\n", (char *) arg);
  return NULL;
Int main(int argc, char *argv[]) {
  pthread t p1, p2;
  int rc:
  printf("main: begin\n");
  rc = pthread_create(&p1, NULL, mythread, "A");
  assert(rc == 0);
  rc = pthread create(&p2, NULL, mythread, "B");
  assert(rc == 0);
  // join waits for the threads to finish
  rc = pthread join(p1, NULL); assert(rc == 0);
  rc = pthread join(p2, NULL); assert(rc == 0);
  printf("main: end\n");
  return 0;
```

Example 2: multithread with shared objects

```
#include <stdio.h>
#include <assert.h>
#include <pthread.h>
static volatile int counter = 0;
void * mythread(void *arg)
  printf("%s: begin\n", (char *) arg);
  for (int i = 0; i < 1e7; i++)
     counter = counter + 1;
  printf("%s: done\n", (char *) arg);
  return NULL;
int main(int argc, char *argv[])
{
  pthread t p1, p2;
  int rc;
  printf("main: begin (counter = %d)\n", counter);
  rc = pthread_create(&p1, NULL, mythread, "A"); assert(rc == 0);
  rc = pthread create(\&p2, NULL, mythread, "B"); assert(rc == 0);
  rc = pthread_join(p1, NULL); assert(rc == 0);
  rc = pthread join(p2, NULL); assert(rc == 0);
  printf("main: done with both (counter = \%d)\n", counter);
  return 0;
```

Multithreaded programming

- Terms
 - Race condition
 - Critical section
 - Mutual exclusion

- Concurrency Control
 - Where
 - Processes with shared objects
 - Threads
 - How
 - Atomic operations
 - Helps from hardwares: Synchronizing primitives

- POSIX Thread API
 - pthread
 - Thread
 - create, control, destroy...
 - Synchronizing primitives
 - Locks
 - Condition variables
 - Semaphore
 - ...

- pthread_create()
 - Create a thread

- pthread_join()
 - Wait thread complete

```
#include <pthread.h>
int pthread_join(
   pthread_t thread,  // structure of thread
   void **value_ptr  // return value
);
```

Locks (mutex)

```
#include <pthread.h>
int pthread_mutex_lock(pthread_mutex_t *mutex);
int pthread_mutex_unlock(pthread_mutex_t *mutex);
```

```
pthread_mutex_t lock = PTHREAD_MUTEX_INITIALIZER;
int rc;

rc = pthread_mutex_lock(&lock);
assert(rc == 0);
x = x + 1; // or whatever your critical section is
pthread_mutex_unlock(&lock);
```

Conditional variables

```
#include <pthread.h>
int pthread_cond_wait(
    pthread_cond_t *cond,
    pthread_mutex_t *mutex);
int pthread_cond_signal(pthread_cond_t *cond);
```

- Summary
 - Processes with shared address space
 - Concurrency control
 - Critical section, race condition
 - POSIX thread library
 - pthread.h

- Protect critical sections
 - Lock
 - lock(), unlock()
- Synchronize different threads
 - Conditional variable
 - signal(), wait()

Protect critical sections

```
void func() {
    Thread 1

/* start */

/* end */

Thread 2
```

```
void func() {

lock()
/* start */

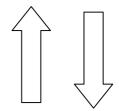

/* end */
unlock()
}
```

Synchronize threads

```
void func1() {
...
/* wait some condition becomes true*/
...
}
```

```
void func2() {
...
/* set the condition */
...
}
```

Thread 1

Thread 2

Also called

- 1. Message passing
- 2. Communication
- 3. Syncronization

Synchronize threads

```
void func1() {
...
/* wait some condition becomes true*/
wait(condition_variable)
...
}
```

```
void func2() {
...
/* set the condition */
signal(condition_variable)
...
}
```

Lock: a variable

```
lock_t mutex; // some globally-allocated lock 'mutex'
...
lock(&mutex);
balance = balance + 1; // critical section
unlock(&mutex);
```

- Around critical sections
- Two states: free(unlocked) or held(locked)

- Two APIs
 - lock():
 - try to acquire the lock
 - If the lock is free (no other thread hold the lock)
 - Get the lock and enter the critical section
 - Won't return while the lock is not free
 - unlock():
 - The state of the lock is changed to free
 - One waiting thread (stuck by lock()) gets the lock

- Revoke some control from OS
 - Threads are scheduled by OS
 - Lock provide a way for programmers to break the scheduling

- How to implement a lock?
 - Criteria
 - Correctness
 - Fairness
 - Performance

Lock implementation: disable interrupts

```
void lock(){
    disable_interrupts();
}

void unlock(){
    enable_interrupts();
}
```

Problems

- Require privileged operations
- Only works for the single processor case

Lock implementation: using flag

```
typedef struct lock t { int flag; } lock t;
void init(lock t *mutex) {
  mutex->flag = 0; // 0 -> lock is free, 1 -> held
void lock(lock t *mutex) {
  while (mutex->flag == 1) // TEST the flag
                            // spin-wait (do nothing)
  mutex - > flag = 1;
                      // now SET it!
void unlock(lock t *mutex) {
  mutex->flag = 0;
```

- Lock implementation: using flag
 - Correctness

```
Thread 1

call lock()

while (flag == 1)

interrupt: switch to Thread 2

call lock()

while (flag == 1)

flag = 1;

flag = 1; // set flag to 1 (too!)
```

- Efficiency
 - Waste CPU time

Lock implementation: atomic test-and-set

```
int TestAndSet(int *old_ptr, int new) {
   int old = *old_ptr; // fetch old value at old_ptr
   *old_ptr = new; // store 'new' into old_ptr
   return old; // return the old value
}
```

Atomically! Hardware Instructions

- In x86
 - xchg

- Lock implementation: atomic test-and-set
 - Spin lock
 - Requires a preemptive scheduler

```
typedef struct lock t { int flag; } lock t;
void init(lock t *mutex) {
  mutex->flag = 0; // 0 \rightarrow lock is free, 1 -> held
void lock(lock t *mutex) {
  while (TestAndSet(\&lock->flag, 1)== 1)
                            // spin-wait (do nothing)
void unlock(lock t *mutex) {
  mutex->flag = 0;
```

- Lock implementation: atomic test-and-set
 - Spin lock
 - Correctness
 - Yes
 - Fairness
 - No guarantees
 - Performance
 - Spin using CPU cycles
 - Single processor: painful
 - Multiple processors: reasonable

- Other hardware primitives
 - test-and-set
 - Compare-and-swap
 - Load-linked and store-conditional
 - Fetch-and-add
 - Fairness: assign a ticket for each waiting thread

```
typedef struct __lock_t { int flag; } lock_t;
void init(lock_t *mutex) {
  mutex->flag = 0;
}
void lock(lock t *mutex) {
  while (mutex->flag == 1)
  mutex->flag = 1;
void unlock(lock_t *mutex) {
  mutex > flag = 0;
}
```

```
typedef struct __lock_t { int flag; } lock_t;
void init(lock_t *mutex) {
  mutex->flag = 0;
void lock(lock_t *mutex) {
  while (TestAndSet(&lock->flag, 1)== 1)
void unlock(lock t *mutex) {
  mutex -> flag = 0;
}
```

Buggy flag

Spin lock

- Problems of spin locks
 - Waste cpu time
 - N threads, only 1 hold the lock, other thread will spin
 - No guarantee on fairness (in general)
 - starvation
- How to improve?

- Sleep instead of spin
 - Assume an OS primitive yield()
 - Move the caller from running to ready

```
typedef struct lock t { int flag; } lock t;
void init(lock t *mutex) {
                              Problem:
  mutex - > flag = 0;
                              1. cost of context switch is substantia
}
                              2. fairness: still not handled
void lock(lock t *mutex) {
  while (TestAndSet(&lock->flag, 1)== 1)
     yield();
}
void unlock(lock t *mutex) {
  mutex -> flag = 0;
```

```
typedef struct __lock_t { int flag; } lock_t;
void init(lock t *mutex) {
  mutex->flag = 0;
void lock(lock t *mutex) {
  while (TestAndSet(&lock->flag, 1)== 1)
void unlock(lock t *mutex) {
  mutex->flag = 0;
```

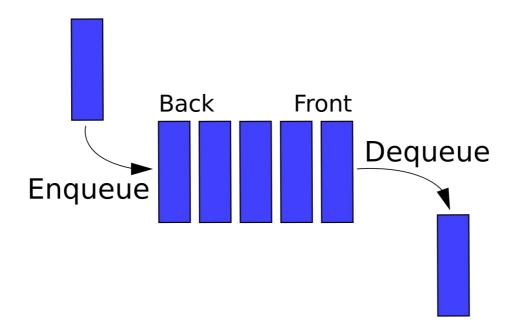

```
typedef struct __lock_t { int flag; } lock_t;
void init(lock t *mutex) {
  mutex->flag = 0;
void lock(lock t *mutex) {
  while (TestAndSet(&lock->flag, 1)== 1)
     yield();
}
void unlock(lock t *mutex) {
  mutex->flag = 0;
}
```

Spin lock

Sleep instead of spin

Question: How to improve fairness?

- Improve fairness
 - Queue

Improve fairness

```
typedef struct __lock_t { int flag; } lock_t;
queue t q;
void init(lock t *mutex) {
  mutex->flag = 0;
  init queue(q);
void lock(lock t *mutex) {
  while (TestAndSet(\&lock->flag, 1)== 1) {
     enqueue(q); // put the thread in q
     yield();
}
void unlock(lock t *mutex) {
  mutex->flag = 0;
  dequeue(q); // wakeup a thread in q
}
```

enqueue/dequeue should be thread-safe.

How to?

- 1. play queue operations in kernel
- 2. spin lock for the queue operation.

- Improve fairness
 - Assume two OS primitives (from Solaris)
 - park(): put the calling thread to sleep
 - unpark(tid): wake a particular thread
 - A parked thread wakes up when an unpark is called.
 - A queue: prevent starvation

```
typedef struct __lock_t {
   int flag;
   int guard;
   queue_t *q;
} lock_t;

void lock_init(lock_t *m) {
   m->flag = 0;
   m->guard = 0;
   queue_init(m->q);
}
```

Questions:

- does it avoid spin? does guard necessary?
- 2. can we change order?
- 3. why no flag=0 in unlock?
- 4. wakeup/waiting race

```
void lock(lock t *m) {
  while (TestAndSet(\&m->guard, 1) == 1)
     ; //acquire guard lock by spinning
  if (m->flag == 0) {
    m->flag = 1; // lock is acquired
    m->guard = 0;
  } else {
     queue add(m->q, gettid());
     m->guard = 0;
                       setpark();
     park();
                       m->guard = 0;
                       park();
void unlock(lock t *m) {
  while (TestAndSet(\&m->guard, 1) == 1)
    ; //acquire guard lock by spinning
  if (queue empty(m->q))
    m->flag = 0; // no one wants it
  else
     m->flag=0;
    unpark(queue remove(m->q));
  m->guard = 0;
```

- sleeping instead of spin + spin on queue
 - Two OS(Soloari) primitives
 - park(), setpark()
 - unpark()
 - Avoid spinning by guard
 - Avoid starvation by a queue

- Queue in kernel (the linux way)
 - OS primitive: futex
 - A memory location
 - A in-kernel queue (for every futex)

- Futex: wait and wake
 - futex_wait(address, expected)
 - If (*address == expected)
 - put caller in the queue, let it sleep
 - else
 - Return immediately
 - futex_wake(address)
 - Wake one thread waiting for the futex
- Let's see some real code (lowlevellock.h of glibc)

```
void mutex_lock (int *mutex) {
  int v;
  // Bit 31 was clear, we got the mutex (this is the fastpath)
  if (atomic_bit_test_set (mutex, 31) == 0)
     return:
  atomic_increment (mutex);
  while (1) {
     if (atomic_bit_test_set (mutex, 31) == 0) {
       atomic_decrement (mutex);
       return;
    }
     /* We have to wait now. First make sure the futex value
       we are monitoring is truly negative (i.e. locked). */
     v = *mutex;
     if (v >= 0)
       continue;
     futex_wait (mutex, v);
void mutex_unlock (int *mutex) {
```

- Lock implementation: two-phase locks
 - park/futex are system call!
 - Spinning could be useful when the lock is about to release
- Two-phase locks
 - In the first phase: spins for a while
 - In the second phase: sleep and wait
 - Hybrid approach
- Above Linux lock is a two-phase lock
 - Spin only once

Can you implement a two-phase lock in your project?

- Lock implementation: summary
 - Disable interrupts
 - Flag
 - Spin locks
 - Test-and-set
 - Compare-and-swap
 - Fetch-and-add
 - Sleep instead of spinning
 - park(), setpark(), unpark()
 - Futex
 - Two-phase locks

- Lock
 - Protect critical sections
- Condition Variables
 - A thread wait some condition becomes true
 - Another thread signal changes of the condition
 - wait(), signal()

```
void *child(void *arg) {
  printf("child\n");
  // XXX how to indicate we are done?
  return NULL;
int main(int argc, char *argv[]) {
  printf("parent: begin\n");
  pthread t c;
  Pthread create(&c, NULL, child, NULL);
  // XXX how to wait for child?
  printf("parent: end\n");
  return 0;
```

```
volatile int done = 0;
void *child(void *arg) {
  printf("child\n");
                                 1. Waste CPU cycles
  done = 1;
                                 2. May be incorrect
  return NULL;
int main(int argc, char *argv[]) {
  printf("parent: begin\n");
  pthread t c;
  Pthread create(&c, NULL, child, NULL);
  while (done == 0)
  printf("parent: end\n");
  return 0;
```

Definition

- A CV is an explicit queue
- Threads put themselves on the queue when some condition is not satisfied, and sleep
- Some other threads change the condition, and wake one/more threads in the queue
- Two API associated with a CV
 - wait()
 - signal()

POSIX calls (pthread.h)

```
#include <pthread.h>

// declear
pthread_cond_t c;

// wait()
int pthread_cond_wait(pthread_cond_t *c, pthread_mutex_t *m);

// signal()
int pthread_cond_signal(pthread_cond_t *c);
```

```
int done = 0;
pthread_mutex_t m = PTHREAD_MUTEX_INITIALIZER;
pthread_cond_t c = PTHREAD_COND_INITIALIZER;
void *child(void *arg) {
  printf("child\n");
  thr_exit();
  return NULL;
int main(int argc, char *argv[]) {
  printf("parent: begin\n");
  pthread_t p;
  Pthread_create(&p, NULL, child, NULL);
  thr_join();
  printf("parent: end\n");
  return 0:
```

```
int done = 0:
pthread mutex t m = PTHREAD MUTEX INITIALIZER;
pthread cond t c = PTHREAD COND INITIALIZER;
void thr_exit() {
                                            pthread_cond_signal(&c)
  Pthread_mutex_lock(&m);
                                             Wakeup a waiting thread on c
  done = 1:
  Pthread_cond_signal(&c);
  Pthread mutex unlock(&m);
void *child(void *arg) {
  printf("child\n");
  thr exit();
  return NULL:
                                            pthread cond wait(&c, &m)
void thr_join() {
                                            1. assume the lock is held
  Pthread_mutex_lock(&m);
                                            2. put caller at the queue
  while (done == 0)
                                               release the lock
     Pthread cond wait(&c, &m);
                                               let caller sleep
  Pthread_mutex_unlock(&m);
                                            3. when wakeup:
                                               - re-acquire the lock,
int main(int argc, char *argv[]) {
                                               - pop from the queue
  printf("parent: begin\n");
  pthread t p;
  Pthread create(&p, NULL, child, NULL);
                                            Consider two possibilities:
  thr_join();
                                            1. parent first
  printf("parent: end\n");
                                            2. child first
  return 0:
```

```
int done = 0:
                                                     Alternative 1: No "done"
pthread mutex t m = PTHREAD MUTEX INITIALIZER;
pthread cond t c = PTHREAD COND INITIALIZER;
void thr_exit() {
                                           void thr exit() {
  Pthread_mutex_lock(&m);
                                              Pthread mutex lock(&m);
  done = 1:
                                              Pthread_cond_signal(&c);
  Pthread_cond_signal(&c);
                                              Pthread mutex unlock(&m);
  Pthread mutex unlock(&m);
void *child(void *arg) {
  printf("child\n");
  thr exit();
  return NULL:
                                           void thr_join() {
void thr_join() {
                                              Pthread_mutex_lock(&m);
  Pthread_mutex_lock(&m);
                                              Pthread_cond_wait(&c, &m);
  while (done == 0)
                                              Pthread mutex unlock(&m);
    Pthread cond wait(&c, &m);
  Pthread_mutex_unlock(&m);
int main(int argc, char *argv[]) {
  printf("parent: begin\n");
  pthread t p;
  Pthread create(&p, NULL, child, NULL);
  thr_join();
  printf("parent: end\n");
  return 0:
```

```
int done = 0;
                                                     Alternative 1: No "done"
pthread mutex t m = PTHREAD MUTEX INITIALIZER;
pthread cond t c = PTHREAD COND INITIALIZER;
void thr exit() {
   Pthread mutex_lock(&m);
   Pthread cond signal(&c);
   Pthread mutex unlock(&m);
}
void *child(void *arg) {
  printf("child\n");
  thr exit();
  return NULL;
void thr join() {
   Pthread mutex lock(&m);
   Pthread cond wait(&c, &m);
   Pthread mutex unlock(&m);
}
int main(int argc, char *argv[]) {
  printf("parent: begin\n");
  pthread t p;
  Pthread create(&p, NULL, child, NULL);
  thr_join();
  printf("parent: end\n");
  return 0:
```

```
int done = 0:
                                                      Alternative 2: No lock
pthread mutex t m = PTHREAD MUTEX INITIALIZER;
pthread cond t c = PTHREAD COND INITIALIZER;
void thr_exit() {
                                            void thr exit() {
  Pthread_mutex_lock(&m);
                                               done = 1;
  done = 1:
                                               Pthread_cond_signal(&c);
  Pthread_cond_signal(&c);
                                             }
  Pthread mutex unlock(&m);
void *child(void *arg) {
  printf("child\n");
  thr exit();
  return NULL:
                                            void thr_join() {
void thr_join() {
                                               if (done == 0)
  Pthread_mutex_lock(&m);
                                               Pthread_cond_wait(&c);
  while (done == 0)
                                             }
     Pthread cond wait(&c, &m);
  Pthread_mutex_unlock(&m);
int main(int argc, char *argv[]) {
  printf("parent: begin\n");
  pthread t p;
  Pthread create(&p, NULL, child, NULL);
  thr_join();
  printf("parent: end\n");
  return 0:
```

```
int done = 0:
                                                       Alternative 2: No lock
pthread mutex t m = PTHREAD MUTEX INITIALIZER;
pthread cond t c = PTHREAD COND INITIALIZER;
 void thr_exit() {
   done = 1;
   Pthread_cond_signal(&c);
 }
void *child(void *arg) {
  printf("child\n");
  thr_exit();
  return NULL:
 void thr_join() {
   if (done == 0)

  return 0:
```

- Summary
 - A queue
 - Wait() and signal()
 - Hold the lock!

Project 4

The Dark Forest of Threads
